TRENDING NOW

AI found more bugs than the team could fix

A major open source project delayed its release because of this

- AI code review surfaced more issues than maintainers could triage
- Release pushed back, not because the AI failed, but because it worked
- Discussion spread fast across HN within hours

WHAT'S HAPPENING

Detection got easy. Fixing didn't.

The bottleneck just moved to a different part of the pipeline

- AI reviewers scan every line, every PR, every time
- Humans still have to read, judge, and fix each finding
- More findings doesn't mean more fixing capacity

WHY IT MATTERS

Catch rate was never the hard part

Most teams measured the wrong thing

- Bug detection scales with compute
- Bug triage scales with human attention
- Scaling one without the other just creates backlog

THE MECHANISM

Where the new bottleneck actually sits

Three stages, only one of them got faster

- Detection: AI reviews code continuously, cheaply, at scale
- Triage: someone still has to decide what's real and what's noise
- Fixing: someone still has to write and test the fix

LESSON ONE

More findings isn't automatically progress

A pile of valid bugs you can't act on is still a pile

- Unaddressed findings create their own kind of risk
- Teams need a plan for volume before they add detection
- Visibility without capacity just creates anxiety

LESSON TWO

Severity triage has to happen before humans do

Not every finding deserves the same attention

- AI can pre-rank findings by likely impact and confidence
- Low-confidence or low-severity items can wait or auto-close
- This keeps human review focused on what actually matters

LESSON THREE

Release processes need to expect this now

Delaying a release because review worked is a new kind of problem

- Build buffer time into release cycles for triage, not just testing
- Decide in advance what blocks a release vs what gets tracked
- Treat AI review output as a queue, not a one-time report

TAKEAWAY

Before adding AI review, plan the queue

Detection without a triage system just moves the problem

- Map who owns triage before you turn on AI code review
- Set thresholds for what's release-blocking vs backlog
- Measure time-to-resolution, not just issues-found

CTA

Where would this backlog hit your team?

If you're rolling out AI review, the triage plan matters more than the tool

- What's your process for handling a sudden spike in findings?
- Happy to compare notes on how teams are structuring this
